Pakistan Fatalities YoY

Pakistan sits at the intersection of three major fault lines — the Afghanistan conflict, the India rivalry, and the US-Iran tension. This tracker examines what drives Pakistan's diplomatic choices and whether deteriorating diplomatic signals can predict future regional conflicts. Current status: 56K fatalities, 19K conflict events, India tone at -0.81 — Pakistan's only net negative major relationship.

When states move toward war, do their economies signal it first? Energy prices are among the few indicators that respond to geopolitical stress in real time — reflecting supply fears, sanctions anticipation, and shifting trade relationships before any formal diplomatic breakdown is declared. This page examines whether rising oil and petrol prices preceded the deterioration in Pakistan's diplomatic tone, and whether commodity markets were effectively pricing in the US-Iran conflict years before it began.

Proxy here being inverse, the higher the value the of line chart the better the relationship is

Peak Risk Year

Can a conflict be predicted by combining what the economy says with what diplomacy shows? Individual indicators have known blind spots — markets can spike without war, and diplomatic scores can decline without escalation. But when economic stress and diplomatic deterioration converge in the same window, the historical pattern becomes harder to dismiss. This page asks whether that convergence was visible in the data early enough to have made a difference.

Can We Predict Future Conflicts?

Pre-Crisis Warning Score — 2024 Spike Preceded the Crisis

In 2024, Iran Tone Momentum crashed to -2.33 and USA Momentum fell to -0.40 — both negative simultaneously, Pre-Crisis Score hit +3, Conflict Risk Score reached 4. Every warning signal fired together. That year coincided with the Gaza conflict peak and maximum Pakistan-Iran diplomatic stress. Today both momentums are positive — Iran +0.17, USA +0.07 — and Conflict Risk Score stands at 0. However the 2026 Iran war is active. The annual model shows recovery because 2025 posted the sharpest single-year diplomatic rebound in the dataset, absorbing the June 2025 Twelve-Day War within its yearly average.

All

Year

2026

The annual model catches slow-building crises — 2024 Pre-Crisis Score hit +3 before the Gaza escalation peak. But sudden conflicts require monthly monitoring. June 2025: both Iran and USA momentum turned negative simultaneously, Conflict Risk Score reached 2 — the Twelve-Day War began June 13. January 2026: Iran Momentum dropped to -0.73, score elevated to 1 — Operation Epic Fury launched February 28, 2026. The model provided a 4-week leading signal. February 2026 itself showed score 0 because the strikes launched on the final day of the month, after GDELT data had already settled.
